

A short summary about the conductive heat transfer :

- Heat transfer can occur either by **conduction**, **convection** or **radiation**.
- Heat transfer through the wall of a house can be modeled as steady and one-dimensional.
- The temperature of the wall in this case depends on one direction only(say the x-direction) and can be expressed as $T(x)$.
- The rate of heat conduction through a plane wall:
 - ① Is proportional to the average thermal conductivity, the wall area, and the temperature difference. \uparrow
 - ② But is inversely proportional to the wall thickness. (For example, the thicker the wall, the less heat goes through it.) \downarrow
 - ③ Once the rate of heat conduction is available, the temperature $T(x)$ at any location x can be determined by replacing T_2 by T , and L by x
 - ④ Under steady conditions, the temperature distribution in a plane wall is a straight line: $dT/dx = \text{const}$

Exercise: find the rate of heat transfer

with $L = 0.4 \text{ m}$, $A = 20 \text{ m}^2$, $\Delta T = 25$, and $k = 0.78 \text{ W/m K}$

using both simple method and using the resistance concept.

Simple method

$$\dot{Q} = kA \frac{\Delta T}{L} = 0.78 \frac{\text{W}}{\text{mK}} * 20 \text{m}^2 * \frac{25 \text{K}}{0.4 \text{m}} = 975 \text{W}$$

Using the resistance concept

$$R_{\text{wall}} = \frac{L}{kA} = \frac{0.4 \text{m}}{\frac{0.78 \text{W}}{\text{mK}} * 20 \text{m}^2} \approx 0.0256 \text{K/W}$$

$$\dot{Q} = \frac{\Delta T}{R_{\text{wall}}} = \frac{25 \text{K}}{0.0256 \text{K/W}} \approx 976.6 \text{W}$$
